Abstract: - Flow through a variable permeability Brinkman porous layer with quadratic permeability function, underlain by a Darcy porous layer of variable linear permeability function is analyzed. The model flow demonstrates the compatibility between the low-order Darcy law and the Brinkman equation in the sense that at the sharp interface between the layers it is possible to impose equality of the non-zero shear stresses. A matching procedure is also introduced for velocity computation near the point of singularity associated with the resulting Cauchy-Euler equation.

Key-Words: - Variable Permeability, Darcy-Brinkman Layers, Sharp Interface

1 Introduction

The experiments of Beavers and Joseph, [1], on the flow through a channel over a Darcy porous layer, and their proposing a slip flow condition at the interface, represents the starting point of a large volume of research work devoted to this problem. Many excellent reviews on the subject matter and applications of this type of flow are available (cf.[3, 8, 16, 17] and the references therein).

In the study of flow through a channel bounded by a Darcy porous layer, a problem arises with the matching condition at the interface between the porous layer and the channel. At the interface, there exists a shear stress discontinuity, a permeability discontinuity, and the low-order of Darcy’s law makes it incompatible with the Navier-Stokes equations. This incompatibility causes an apparent slip in the fluid velocity at the assumed sharp interface, and has been handled with the Beavers and Joseph’s slip condition, [1], that was intended to interpret the enhancement in the volumetric flow rate in the channel as a result of introducing a porous boundary. Conditions at the interface between a channel and a porous layer are important as they influence mass and heat transfer in the flow domain. This initiated a need for a non-Darcy model to govern the flow in the porous layer, and to be compatible with the Navier-Stokes equations.

While much research has been devoted to the analysis of conditions at the interface between a channel and a porous medium and the types of governing equations that are best suited for the flow through the porous layer, [3, 4, 10, 12, 14, 15, 16, 17], recent advances in the field deal with flow through variable permeability layers, [2, 5, 6, 7, 9, 13], and the analysis of the transition layer that is associated with Brinkman’s equation and proposed by Nield and Koznetsov, [11].

Brinkman’s equation with variable permeability, [7], has been of great utility in the analysis of a transition layer between a Darcy porous layer and a channel through which the flow is governed by Navier-Stokes equations, [11]. However, most of the work carried out on analysis of flow in the transition layer has assumed a Brinkman layer with variable permeability underlain by a constant permeability Darcy layer. Little to no work has provided analysis of the problem of variable permeability porous layer bounding a Brinkman layer of variable permeability. This gives rise to the current work in which we provide analysis of the more general situation wherein the Darcy layer is of variable permeability in order to capture naturally occurring porous layers of different permeability. We do not consider the Brinkman layer as a transition layer in this work; rather, we consider
flow through a two-layer composite configuration, shown in Fig. 1, one Darcy and one Brinkman layer, both possessing variable permeability and both bounded by solid, impermeable walls on opposite sides. The common side between layers is an assumed sharp interface on which we will assume permeability, velocity, and shear stress continuity.

2 Problem Formulation

Consider the steady, unidirectional flow of a viscous fluid through the porous layers shown in Fig. 1, and termed Darcy layer (the lower porous layer where Darcy’s law is valid) and Brinkman layer (the upper porous layer where Brinkman’s equation is valid). Flow in both layers is driven by the same constant pressure gradient, and each layer is of variable permeability. The layers are bounded by solid, impermeable walls at \( y = -D \) and at \( y = D \), and the interface between the layers is an assumed sharp interface, located at \( y = 0 \).

Equations (1) and (2) are to be solved subject to the following conditions:

**Conditions at the interface**, \( y=0 \), are the following velocity continuity, permeability continuity, and continuity of the normal component of shear stress, respectively,

\[
\begin{align*}
Q & = R k_2(y) \\
\mathcal{G} \frac{du}{dy}(0) & = \frac{dv}{dy}(0)
\end{align*}
\] …(3)

**Conditions at the solid walls** are the no-slip conditions and vanishing permeability, respectively, namely

\[
\begin{align*}
\mathcal{U}(D) & = \mathcal{V}(-D) = 0 \\
k_1(-D) & = k_2(D) = 0
\end{align*}
\] …(4)

3 Problem Solution

Assume that the permeability \( k_1(y) \) in the Darcy layer to be an increasing linear function of \( y \), that reaches a maximum value, \( k_{\text{max}} \), at \( y = 0 \), and in the Brinkman layer a quadratic permeability function, \( k_2(y) \), written as

\[
k_1(y) = \frac{(D + y)k_{\text{max}}}{D} \quad \text{and} \quad k_2(y) = (a + by)^2
\] …(5)

then the velocity profile in the Darcy layer is obtained from (2) as
\[
v(y) = R \frac{(D + y)k_{\text{max}}}{D} \quad \text{...(6)}
\]

and a shear stress in the lower layer and at the interface given by

\[
\frac{dv}{dy} = R \frac{k_{\text{max}}}{D}.
\]

Condition (3) thus yields the following expression for velocity at the interface:

\[
u(0) = v(0) = u_i = Rk_{\text{max}}.
\]

Using (3) and (4) gives Brinkman permeability function:

\[
a = \mp \sqrt{k_{\text{max}}},
b = \frac{a}{D} = \pm \sqrt{\frac{k_{\text{max}}}{D}},
k_2(y) = (\sqrt{\frac{k_{\text{max}}}{D}} - y^2)
\]

Choosing \( k_2(y) = (\sqrt{\frac{k_{\text{max}}}{D}} - y^2) \) and letting

\[
Y = 1 - \frac{y}{D},
\]

equation (1) is transformed into the Cauchy-Euler inhomogeneous ordinary differential equations

\[
Y^2 \frac{d^2u}{dY^2} - \frac{D^2}{\partial k_{\text{max}}}u = QD^2Y^2.
\]

General solution to (10) is given by

\[
u = c_1 \left[1 - \frac{y}{D} \right]^{m_1},
\]

\[
+ c_2 \left[1 - \frac{y}{D} \right]^{m_2} + C \left[1 - \frac{y}{D} \right]^2
\]

where

\[
1 + \sqrt{1 + 4 \frac{D^2}{\partial k_{\text{max}}} = m_1
\]

\[
1 - \sqrt{1 + 4 \frac{D^2}{\partial k_{\text{max}}} = m_2
\]

\[
C = \frac{2}{QD^2(2 - m_1)(1 + m_1)}
\]

\[
c_1 = \frac{Rk_{\text{max}}[m_1 + \frac{1}{g} + C[2 - m_1]}
\]

\[
c_2 = \frac{Rk_{\text{max}}[m_1 + \frac{1}{g} + C[2 - m_1]}
\]

Shear stress in the upper layer is obtained from (11) and takes the form

\[
u'(y) = - \frac{c_1m_1}{D} \left[1 - \frac{y}{D} \right]^{m_1-1}
\]

\[
- \frac{c_2m_2}{D} \left[1 - \frac{y}{D} \right]^{m_2-1} - 2C \left[1 - \frac{y}{D} \right]
\]

and has the following value at the interface, \( y = 0 \):

\[
\frac{du}{dy}(0) = - \frac{c_1m_1}{D} - \frac{c_2m_2}{D} + 2C.
\]

Solution to the given problem is thus completely determined and can be expressed in dimensionless form using the following dimensionless variables:

\[
y^* = \frac{y}{D}; u^* = \frac{\mu u}{(-p_\text{s})D^2}; v^* = \frac{\mu v}{(-p_\text{s})D^2};
\]

\[
k^*_i(y) = \frac{k_i(y)}{D^2} = k^*_i(yD) = k^*_i(y^*);
\]

\[
k^*_{\text{max}} = \frac{k_{\text{max}}}{D^2}.
\]
The dimensionless porous layers span the following dimensionless length $y^*$: Darcy layer: $-1 \leq y^* \leq 0$ and $0 \leq y^* \leq 1$ for Brinkman layer. Dimensionless velocity profiles in the Brinkman and Darcy layers are given by the following equations, respectively

$$u^* = \left( k_{\text{max}}^* \left[ \frac{\partial m^*}{\partial m^*} + 1 \right] + \frac{1}{\partial(m^* - 2) m^*} \right) \times \left[ 1 - y^* \right]^2 \left( \left[ \frac{\partial m^*}{\partial m^*} + 1 \right] + \frac{1}{\partial(m^* - 2) m^*} \right) \times \left[ 1 - y^* \right]^2 - \left( \frac{1}{\partial(2 - m^*) (2 - m^*)} \right) \left[ 1 - y^* \right]^2 $$

$$v^* = k_1^*(y^*) = k_{\text{max}}^* (1 + y^*).$$

Dimensionless permeability distributions in the lower and upper layers are given respectively by

$$k^*_1(y) = k_{\text{max}}^* (1 + y^*) \right \}
$$

$$k^*_2(y) = k_{\text{max}}^* (1 - y^*)^2 \right \}
$$

while the dimensionless velocity and shear stress at the interface are given, respectively, by

$$u_i^* = k_{\text{max}}^* \right \} \right \}
$$

$$\frac{du^*}{dy^*}(0) = \frac{k_{\text{max}}^*}{\partial} \right \} \right \}
$$

4 Results and Discussion

The dimensionless equations (17) to (22), above, are dependent on the parameters $k_{\text{max}}^*$ and $\partial$. The parameter $\partial = \frac{\mu_{\text{eff}}}{\mu}$ is the ratio of effective viscosity to the fluid viscosity. In the absence of concrete experimental or theoretical evidence supporting its value, we will take the full range of values $\partial = 0.5, 0.95, 1, 1.05, \text{and} 1.5$. The parameter $k_{\text{max}}^*$ is the dimensionless permeability at the interface. It is in fact the dimensionless Darcy number, $Da$, which has a maximum value of unity. In this analysis we take the following range of values for $k_{\text{max}}^*$: 1, 0.1, 0.01, 0.001, 0.0001, and 0.00001.

Using the above values of $k_{\text{max}}^*$ and $\partial$, we provide the following data for velocity and shear stress at the interface, velocity profiles, and permeability distributions in the layers.

4.1 Velocity and Shear Stress at the Interface

Equation (21) provides an expression for the dimensionless velocity $u_i^*$ at the interface in terms of the dimensionless permeability $k_{\text{max}}^*$. It is clear and expected that as $k_{\text{max}}^*$ decreases, the dimensionless velocity at the interface decreases. Furthermore, this dimensionless velocity is independent of $\partial$. Dependence of the dimensionless velocity at the interface on viscosity, pressure gradient and on the dimensional permeability at the interface is given by equation (8), or $u_i = -\frac{p_{\text{eff}}}{\mu} k_{\text{max}}$, which shows its increase with increasing permeability and magnitude of pressure gradient, and its decrease with increasing fluid viscosity, $\mu$. For a given $\mu_{\text{eff}}$, an increase in $\mu$ results in a decrease in $\partial$. We can then conclude that the dimensionless velocity at the interface decreases with decreasing $\partial$.

Equation (21) gives an expression for the dimensionless normal component of velocity derivative at the interface. While the expression $\frac{\partial u_i^*}{\partial y^*}(0)$ is given by $k_{\text{max}}^*$, hence has the same values as the dimensionless velocity at the interface, its dimensional expression shows its dependence on the pressure gradient, fluid viscosity and depth of the lower porous layer. Magnitude of this term is inversely proportional to the depth of the lower porous layer. In fact, in the limit as $D$ approaches
infinity, shear stress at the interface approaches zero (the value of shear stress at the interface as given by Darcy’s law with constant permeability).

### 4.2 Dimensionless Permeability Distribution

Equation (20) gives the expressions of the dimensionless permeability distributions in the Darcy and Brinkman layers, respectively. The linear profile starts at zero on the lower bounding wall, and increases till it reaches $k_{\text{max}}^*$ at the interface. In the upper layer, the dimensionless permeability profile is parabolic with a maximum value at the interface and falls to zero on the upper boundary. Graphs of the two permeability profiles are shown in Figure 2 for the range of $k_{\text{max}}^*$ (Darcy number) of 0.1 and 1.

**Fig. 2. Permeability Distribution in the Two Layers**

### 4.3 Velocity Profiles in the Porous Layers

Dimensionless velocity profiles in the upper and lower layers are given, respectively, by equations (17) and (18). While the profile in the lower layer is dependent on $k_{\text{max}}^*$, the profile in the upper layer depends on both $k_{\text{max}}^*$ and $\delta$. The values of the velocity in the upper layer become asymptotically large as we get close to the upper boundary. Inherent in the Cauchy-Euler equation is the ordinary point of singularity (zero of the coefficient of the highest derivative). Boundary conditions do not remove this singularity. Therefore, solution is valid near the point of singularity. We therefore follow the steps below to generate velocity values near the upper wall. Taking the limit of $u^*$ as $y^* \to 1^-$, we obtain:

\[
\lim_{y^* \to 1^-} u = 0 = c_1 \lim_{y^* \to 1^-} [1 - y^*]^m_1 + c_2 \lim_{y^* \to 1^-} \frac{1}{[1 - y^*]^{m_2}} + \lim_{y^* \to 1^-} C[1 - y^*]^2
\]  

...(23)

Noting that $\lim_{y^* \to 1^-} [1 - y^*]^m_1 = 0$,

\[
\lim_{y^* \to 1^-} C[1 - y^*]^2 = 0 \text{ and } \lim_{y^* \to 1^-} \frac{1}{[1 - y^*]^{m_2}} = +\infty,
\]

we need

\[
c_2 \lim_{y^* \to 1^-} \frac{1}{[1 - y^*]^{m_2}} \to 0, \text{ or } c_2 = 0.
\]

Therefore, near $y^* = 1$, we have

\[
u = c_1 [1 - y^*]^m_1 + C[1 - y^*]^2
\]  

...(24)

Velocity computations thus proceed as follows:

1) Use equation (17) to calculate the velocity up to the edge of boundary layer.
2) Use equation (24) to calculate the velocity from the edge of boundary layer to the upper boundary.

In order to calculate the limits of the boundary layer, we use definition of the boundary layer thickness, $\delta$, as square root of the permeability, namely

\[
\delta = \sqrt{k_2^*(y^*)} = \sqrt{k_{\text{max}}^* (1 - y^*)}
\]  

...(25)

Now, $y^* \geq \delta \Rightarrow$

\[
y^* \geq \sqrt{k_{\text{max}}^*(1 - y^*)} = \sqrt{k_{\text{max}}^*} - y^* \sqrt{k_{\text{max}}^*}
\]

or $y^* (1 + \sqrt{k_{\text{max}}^*}) \geq \sqrt{k_{\text{max}}^*}$. Hence

\[
y^* \geq \frac{\sqrt{k_{\text{max}}^*}}{(1 + \sqrt{k_{\text{max}}^*})}.
\]  

...(26)
Critical values of $y^*$ for different $k^*_\text{max}$ are listed in Table 1 below. Therefore, we use equation (17) to calculate the velocity up to the critical value of $y^*$, and equation (24) to calculate the velocity for $y^* < y < 1$.

**Table 1.** Critical Values of $y^*$ for different $k^*_\text{max}$.

While the above decomposition of the flow domain seems reasonable it does however result in a jump in the velocity at $y = \frac{\sqrt{k^*_\text{max}}}{(1 + \sqrt{k^*_\text{max}})}$, as can be seen in Figs. 3 and 4, below, which illustrate the velocity profiles for $\vartheta = 1$ and different values of $k^*_\text{max}$. This points to the need for matching the two solutions at the point of jump discontinuity, as explained below.

**Fig. 3** Velocity Profiles $u^*(y), v^*(y)$, for $\vartheta = 1$ and different values of $k^*_\text{max}$.

**Fig. 4** Velocity Profiles $u^*(y), v^*(y)$, for $k^*_\text{max} = 1$, and different values of $\vartheta$. 
Figure 1 represents the matching configuration and illustrates three regions in the flow domain: the lower region where Darcy’s law is valid; the middle region where Brinkman’s equation and its solution, given by equation (17), are valid, and the boundary layer region which in which equation (24) is valid. We can thus state the velocity profile in the Brinkman layer as follows:

\[
\mathbf{u}^* = \mathbf{u}_1^* = B_1 [1 - y^*]^m_1 - B_2 [1 - y^*]^m_2 - B_3 [1 - y^*]^b
\]

...(27)

when \(0 < y < 1 - \delta\)

and

\[
\mathbf{u}_2^* = \mathbf{u}^*_2 = B_1 [1 - y^*]^m_1 - B_3 [1 - y^*]^b
\]

...(28)

when \(1 - \delta < y < 1\)

where

\[
B_1 = \left\{ \frac{k^*_{\text{max}} [\mathbf{m}_2^* + 1]}{\mathbf{m}_2^* - m_1^*} + \frac{1}{\mathbf{m}_2^* (m_2^* - m_1^*)} \right\}
\]

...(29)

\[
B_2 = \left\{ \frac{k^*_{\text{max}} [\mathbf{m}_1^* + 1]}{\mathbf{m}_1^* - m_2^*} + \frac{1}{\mathbf{m}_1^* (m_1^* - m_2^*)} \right\}
\]

...(30)

\[
B_3 = \left\{ \frac{1}{\mathbf{m}_1^* (2 - m_1^*) (2 - m_2^*)} \right\}
\]

...(31)

Now, for velocity continuity at \(y = 1 - \delta\) we must match \(u_2^*\) with \(u_1^*\) by letting

\[
\mathbf{u}_2^* = B_1 [1 - y^*]^m_1 - A [1 - y^*]^b
\]

...(32)

when \(1 - \delta < y < 1\)

and

\[
\mathbf{u}_1^* (1 - \delta) = \mathbf{u}_2^* (1 - \delta).
\]

...(33)

Equations (27)-(33) yield

\[
A = B_2 - B_3 \delta^{m_2^* - 2}
\]

...(34)

\[
\mathbf{u}_2^* = B_1 [1 - y^*]^m_1 - (B_2 - B_3 \delta^{m_2^* - 2}) [1 - y^*]^b
\]

...(35)

when \(1 - \delta < y < 1\).

Now, using (27) and (35), we plot the velocity profiles in the upper layer. In Figures 5 and 6 we illustrate the velocity profile in both layers for \(k^*_{\text{max}} = 0.1\) and 1, and \(\mathbf{\vartheta} = 1\). These graphs show the expected decrease in the velocity in the upper layer as we move away from the interface, and the continuity of velocity at the edge of boundary layer.
Fig. 6 Matched Velocity profiles for $k_{\text{max}} = 0.1, \beta = 1$.

4 Conclusion

In this work we considered the flow of a viscous fluid through a two-layer configuration. The flow through one layer is governed by Darcy’s law with variable permeability, and the other by a Brinkman’s equation with quadratic variable permeability. Brinkman’s equation reduces to a Cauchy-Euler equation. Solution to this equation becomes excessively large for small values of dimensionless maximum permeability. To remedy the arising jump discontinuity in the velocity as we approach the upper boundary, we devised a matching condition that induces velocity continuity at the edge of the boundary layer to the upper solid boundary.
