Abstract: - The paper describes the results of a functional-geometric study of the necessary and sufficient conditions for the existence of a differential realization in the terms of the tensor product of real Hilbert spaces. There are considered continuous infinite-dimensional dynamical system in the class of controlled bilinear non-stationary ordinary differential equations of the second order (including quasi-linear hyperbolic models) in a separable Hilbert space. Therefore the topological and metric conditions for the continuity of the Rayleigh–Ritz operator with the calculation of the fundamental group of its image are analytically substantiated. The results of paper give incentives for generalizations in the qualitative theory of nonlinear structural identification of higher order multi-linear differential models.

Key-Words: - tensor analysis, nonlinear system analysis, differential realization, Rayleigh–Ritz operator.

1 Introduction

Since the qualitative theory of differential realization studies the problems of the existence of analytical representation for a properly defined continuous dynamical system [1], the present article could have the title: How to determine whether bilinear differential “black box” equation exists. Therefore, from a methodological point of view, bilinear differential realization can be considered as an important step towards constructing a general theory of mathematical modeling of complex dynamic systems within the context of the theory of identification of evolutionary equations [2] at the junction of functional analysis [3, 4] and the theory of differential equations in infinite-dimensional spaces [5]. Moreover, in the system-theoretical analysis of the continuous weakly structured systems, up to a certain moment, the qualitative results of finite-dimensional realization theory are “mechanically” transferred to the infinite-dimensional case without particular complications. This applies to both stationary and non-stationary differential models of the first order (parabolic equations and systems of diffusion type) in uniformly convex Banach spaces [6] and separable Hilbert spaces [7, 8].
Significant analytical difficulties can be faced when moving to constructing a differential realization with a dynamic order higher than the first. This includes the non-nominal consideration of the structure of hyperbolic models, the representations of which cannot dispense with taking into account the nonlinearity of their dynamics, in particular, the bilinear structure of the implementation model, which is the focus of attention in this article. At the same time, we show that, throwing the analytical bridge between projective geometry and the differential realization of simulated infinite-dimensional dynamic processes, the structure of projectivization of the non-linear functional Rayleigh model, which is the focus of attention in this article, is permissible.

2 Problem Formulation

Further on, \((X_1||y_1), (Y_1||y_1), (Z_1||z_1)\) are real separable Hilbert spaces (that is, norms satisfy “the condition of parallelogram”); with that, below we use \([3, p. 176]\) the linear isometry (preserving the norm) \(E:Y \to X\) of the spaces \(Y\) and \(X\). As usual, \(L(\mathcal{B},\mathcal{B}^\sigma)\) is the Banach space (with operator norm) of all linear continuous operators for the Banach spaces \(\mathcal{B}\) and \(\mathcal{B}^\sigma\), \(\mathcal{L}(\mathbb{X}^2,\mathbb{X})\) is the space of all continuous bilinear mappings from the Cartesian square \(\mathbb{X} \times \mathbb{X}\) (with product topology) into the space \(\mathbb{X}\) (similar to \(\mathcal{L}(\mathbb{X}^2,\mathbb{Z})\)).

Let \(T\) denote the segment of the number scale \(R\) with the Lebesgue measure \(\mu\), and \(\varphi_\mu\) denote the \(\sigma\)-algebra of all \(\mu\)-measurable subsets out of \(T\), the notation of \(S \subseteq Q\) for \(S, Q \in \varphi_\mu\) means \(\mu(S \Delta Q)=0\).

Additionally, we assume that \(AC^1(T,\mathbb{X})\) is the set of all functions \(\varphi: T \to \mathbb{X}\), the first derivative of which is absolutely continuous function (with respect to measure \(\mu\) on the interval \(T\).

If below \((\mathcal{B},\mathcal{B}||y_1)\) is some Banach space, then let \(L_p(T,\mathcal{B})\), \(p \in [1, \infty]\) denote the Banach space of all classes of \(\mu\)-equivalence of all Bochner-integrable mappings \(f:T \to \mathcal{B}\) with norm \(\|f\|_p^\mu = \left(\int_T \|f(t)\|^p d\mu(t)\right)^{1/p}\), respectively, let \(L_{\infty}(T,\mathcal{B})\) denote the Banach space of data of classes with norm ess sup \(T\|f\|_p^\mu\). In this context, we agree that
\[
L_2 := L_2(T, L(X,X)) \times L_2(T, \mathcal{L}(X^2,\mathbb{X})) \times L_2(T, \mathcal{L}(X^2,\mathbb{X})) \\
\times L_2(T, \mathcal{L}(X^2,\mathbb{X})) \times L_2(T, \mathcal{L}(X^2,\mathbb{X}))
\]

Further, we believe that, on the time interval \(T\), the behavior \([1,6, 15]\) of the studied behavioral system in the form of a nonlinear bundle of controlled nonlinear dynamic processes (controlled trajectory curves) of the “input-output” type is recorded (possibly a posteriori), i.e. formally:

\[
N \subset \{(x,u): x \in AC^1(T,\mathbb{X}), u \in L_2(T,\mathbb{Y})\}
\]

\[
\text{Card}N \leq \text{exp}S_0\)_{N_0}
\]

where \((x,u)\) is the pair “trajectory, program control”, \(S_0\) is the alef-zero, \(\text{exp}S_0\) is the continuum; the term “nonlinear bundle” means that for the trajectory curves of this bundle the presence of the superposition principle is not assumed a priori \([17, p.18]\), when the dependence of the output quantities \(x()\) on the input actions \(u()\) is linear.

Next, let the statement function for the second derivative (in the implementation model) of the trajectory \(t \mapsto x(t)\) of the form below be given as the inertial-mass characteristic of the simulated system:

\[
A \in L_{\infty}(T, L(X,\mathbb{X}))
\]

\[
\mu\{t \in T: \hat{A}(t) = 0 \in L(X,\mathbb{X})\} = 0;
\]

taking into account further constructions, we assume that the violation of the condition

\[
\mu\{t \in T: \text{Ker} \hat{A}(t) = 0 \in X\} = 0
\]

is permissible.

Let us consider the problem: for the pair \((N, \hat{A})\) defined, determine the necessary and sufficient conditions expressed in terms of a nonlinear bundle of \(N\) dynamic processes and the statement function

\[\text{One of the founders of the realizaton theory, R.E. Kalman, stating that in the general theory of systems the realizaton problem plays a central role [17, p. 267], formulated the following approach [17, p. 286]: to consider the realization problem as an attempt to guess the equations of motion of a dynamic system by the behavior of its input and output signals or as building a physical model that explains the experimental data.}\]
\( \hat{A} \), for the existence of an ordered set of eight statement functions

\[
(A, A_0, B, D_1, D_2, D_3, D_4, D_5) \in L_2,
\]

for which a bilinear differential realization (BDR) of the following form is feasible:

\[
A\frac{d^2x}{dt^2} + A_0 x = Bu + D_1(x, x) + D_2(x, dx/dt) + D_3(dx/dt, dx/dt) + D_4(E(u), x) + D_5(E(u), dx/dt) \quad \forall (x, u) \in N;
\]

equality in (1) is considered as identity in \( L_1(T, X) \).

If the simulated operators of the system (1) are supposed to be searched for in the class of stationary operators, then we will construct them in the class of continuous operators, and write

\[
(A, A_0, B, D_1, D_2, D_3, D_4, D_5) \in L'.
\]

In connection with the indicated mathematical formulation, we note that each area of mathematics, as a rule, contains its major problems, which are so difficult that their complete solution is not even expected, but they stimulate a constant work flow and serve as milestones on the way to progress in this area. In the qualitative theory of differential realization of dynamic systems, such a problem is that of classifying continuous infinite-dimensional behavioristic systems, considered as if they exactly coincided with the solutions of idealized differential models. In the most strong form, it suggests the classification of such systems within the accuracy of the corresponding class of differential realization models, in particular, the class of non-stationary BDR-models (1), which are substantiated below by Theorems 1, 2 (and their corollaries) that allow in the aforementioned classification to significantly approach the ideal combination of functional transparencies and geometric visibility.

3 The Existence of the BDR-Model

We now describe the analytic scheme on the solvability of the BDR-problem (1). So, let \( Z := X \otimes X \) be an updated tensor product [4, p. 64] of Hilbert spaces \( X \) and \( X \) with cross-norm \( \| \|_Z \), defined by the internal product.

Moreover, we accept the following notation:

\[
U := X \times X \times Y \times Z \times Z \times Z \times Z \times Z;
\]

\[
L_2 = L_2(T, L(X, X)) \times L_2(T, L(X, Y)) \times L_2(T, L(Y, Y)) \times L_2(T, L(Z, X)) \times L_2(T, L(Z, Y)) \times L_2(T, L(Z, Z)) \times L_2(T, L(2), L(2, Z));
\]

it is clear that functional space \( L_2 \) (with the topology of the product) is linearly homeomorphic to the Banach space \( L_2(T, L(U, X)) \).

Let \( \pi \) denote the universal bilinear mapping

\[
\pi : X \times X \rightarrow X \otimes X;
\]

in the language of categories, morphism \( \pi \) defines the tensor product as a universally repelling object [16, p. 40]. The universality of the bilinear mapping \( \pi \) also consists in the following relations being satisfied:

\[
\pi(x, x) = \pi(x, x) = \pi(x, x);
\]

\[
\| \pi(x, x) \|_Z = \| \pi(x, x) \|_Z = \| \pi(x, x) \|_Z;
\]

these relations are important for determining the construction of the functional Rayleigh–Ritz operator (2) in terms of specification of the norm

\[
\| \|_Z.
\]

We further believe that the Cartesian square \( X^2 = X \times X \) is endowed with the norm \( (\| \|_X^2 + \| \|_X^2)^{1/2} \).

In this formulation, \( \pi \in \mathcal{I}(X^2, Z) \) holds. Moreover, taking into account Theorems 2 [3, p. 245] for any bilinear mapping \( \mathcal{D} \in \mathcal{I}(X^2, X) \), there exists a linear continuous operator \( \mathcal{D} \in L_1(U, X) \), such that \( \mathcal{D} = \pi \) is feasible. In addition, for any pair \( (x, u) \in N \) the following inclusions will be performed:

\[
\pi(x, x), \pi(x, dx/dt), \pi(dx/dt, dx/dt) \in L_2(T, Z);
\]

\[
\pi(E(u), x), \pi(E(u), dx/dt) \in L_2(T, Z);
\]

these formulations are summarized below by the following statement.

**Lemma 1.** For any set of statement functions

\[
(A, A_0, B, D_1, D_2, D_3, D_4, D_5) \in L_2
\]

and mapping

\[
F : L_2(T, X) \times L_2(T, X) \times L_2(T, Y) \times \prod_{t=1}^5 L_2(T, X^2) \rightarrow L_1(T, X),
\]

\[
(j_1, j_2, j_3, j_4, j_5, j_6, j_7, j_8) \mapsto F(j_1, j_2, j_3, j_4, j_5, j_6, j_7, j_8) = A_1 j_1 + A_2 j_2 + B_1 j_3 + B_2 j_4 + D_3 j_5 + D_4 j_6 + D_5 j_7 + D_6 j_8,
\]

there exists a unique tuple of statement functions

\[
(D_1, D_2, D_3, D_4, D_5, D_6, D_7, D_8) \in \mathcal{I}_2
\]

and, accordingly, a unique linear mapping

\[
M : L_2(T, U) \rightarrow L_1(T, X),
\]

having an analytical representation written as

\[
(z_1, z_2, z_3, z_4, z_5, z_6, z_7, z_8) \mapsto M(z_1, z_2, z_3, z_4, z_5, z_6, z_7, z_8) = D_1 z_1 + D_2 z_2 + D_3 z_3 + D_4 z_4 + D_5 z_5 + D_6 z_6 + D_7 z_7 + D_8 z_8,
\]

such that the following functional equality is satisfied:

\[
(j_1, j_2, j_3, j_4, j_5, j_6, j_7, j_8) \mapsto F(j_1, j_2, j_3, j_4, j_5, j_6, j_7, j_8) =
\]

E-ISSN: 2224-2880

101

Volume 19, 2020
which, in turn, induces the following operator equations for statement functions from the constructions of mappings \( F \) and \( M \):

\[
A = D_1, \quad A = D_2, \quad B = D_3.
\]

\[
D_1 = D_2 \circ \pi, \quad D_2 = D_3 \circ \pi, \quad D_3 = D_1 \circ \pi.
\]

The Lemma 2 generalizes Corollary 1 [6].

Lemma 2. Let \( S, Q \in \varphi_\mu \), then \( S \subseteq Q \), if the following equalities hold:

\[
S = \{ (g(t), m(t), \pi(t), h(t), u(t), \tilde{u}(t)) \mid 0 \in U \},
\]

\[
Q = \{ (g(t), m(t), \pi(t), h(t)) \mid 0 \in U \},
\]

\[
V_N = \text{Spart} \{ (dxdt, x, x), \pi(x, dt), \pi(dxdt, dxdt), \pi(E(u), x), \pi(E(u), dxdt) \} \subseteq L_2(U, V) : (u, u) \in N_0 \}.
\]

Further, let \( L_2(T, R) \) be the convex cone [4, p. 127] of the classes of \( \mu \)-equivalence of all real non-negative functions \( \mu \)-measurable on \( T \), and \( \leq_L \) is such a quasi-ordering in \( L_2(T, R) \) that \( \xi' \leq_L \xi'' \) in case if \( \xi'(t) \leq \xi''(t) \) \( \mu \)-almost everywhere on the interval \( T \). Moreover, for a given \( W \in L_2(T, R) \), by \( \text{sup}_L W \) we denote the smallest upper face for \( W \) if this face exists in the cone \( L_2(T, R) \) in the quasi-ordering structure \( \leq_L \). In particular, the following occurs:

\[
\text{sup}_L \{ \xi', \xi'' \} = \xi' \land \xi'' = 2^{-1} \left( |\xi' + \xi''| + |\xi' - \xi''| \right).
\]

In this formulation, we consider a functional lattice with orthocomplement [4, p. 339]:

\[
\rho(W) := \{ \xi \in L_2(T, R) : \xi \leq L \text{ sup}_L W \}.
\]

Then \( (\rho(W), \leq_L) \) is the lattice with lower \( \chi_0 \in L_2(T, R) \) and upper \( \text{sup}_L W \in L_2(T, R) \) boundaries; here \( \chi_0 \) is the “null-function” of the convex cone \( L_2(T, R) \). Moreover, from Theorems 17 [3, p. 68] and Corollary 1 [3, p. 69] it is easy to extract a more general statement; below \( \text{inf}_L \) is the largest lower \( \leq_L \)-face.

Lemma 3. The functional lattice \( \rho(W) \) is complete, i.e. we can perform inclusions

\[
\text{inf}_L V, \quad \text{sup}_L V = \rho(W), \quad \forall V \subseteq \rho(W).
\]

Let \( \Psi : V_N \rightarrow L_2(T, R) \) be the Rayleigh–Ritz functional operator [7, 8]:

\[
t \rightarrow \Psi(\phi)(t) := \left\{ \begin{array}{ll}
\|g(t)\hat{g}(t)\|_V, & \text{if } \phi \neq 0 \in U; \\
0 & \text{if } \phi = 0 \in U;
\end{array} \right.
\]

where \( \phi := (g, w, v, q, s, h, \hat{u}, \tilde{u}) \in V_N \).

It is clear that the following equality occurs:

\[
\|g(t), m(t), \pi(t), h(t), u(t), \tilde{u}(t)\|_V := \|g(t)\hat{g}(t)\|_V, \quad \text{if } \phi \neq 0 \in U;
\]

\[
0, \quad \text{if } \phi = 0 \in U.
\]

By virtue of Lemma 2, in the time interval \( T \) the following equality holds:

\[
\text{sup}_L \Psi(\phi) = \text{sup}_{\rho(W)} \left\| \hat{g} \right\|_V.
\]

In the definition of the \( \text{sup}_L \)-structure of the function support, we follow [3, p. 137] (that is, the \( \text{sup}_L \)-structure of the function support is determined within the accuracy of a set of measure zero; not to be confused with the \( \text{sup}_L \)-support from [18]).

Nonlinear operator (2) satisfies very simple (but important) relations

\[
\xi_2 \leq \Psi(\phi) = \Psi(\phi), \quad r \in R := R \setminus \{ 0 \}, \quad \phi \in V_N ;
\]

in the designations below we will distinguish the image of the point \( \Psi(\phi) \) and the image of the set \( \Psi(\phi) \).

The theory of the Rayleigh–Ritz operator needs a precise functional-geometric language that makes us pay special attention to this language. So before we go any further, let us introduce additional terminology. Namely, in view of (3), the operator \( \Psi \) induces the mapping

\[
\rho(\gamma) := \frac{\rho(\gamma)}{\rho(\gamma)} , \quad \gamma \in P_N \quad (\gamma \subseteq V_N),
\]

where \( P_N \) is the real projective space associated with linear variety \( V_N \) (with topology induced from space \( L_2(T, U) \)); i.e. \( P_N \) is a set of orbits of the multiplicative group \( R^+ \), acting on \( V_N \). In this geometric interpretation, the key moment is topological properties of space \( P_N \), \( \dim P_N < \infty \), of course, in the first place (within the context of Theorem 2), its compacted-ness. Specifically, if \( \dim V_N = 3 \), then the compact 2-manifold \( P_N \) is arranged as the Möbius loop, to which a circle is glued along its border [13, p. 162]. As a side note, we can state that on \( P_N \) one can introduce the structure of the \( CW \)-complex, which, in turn, simplifies the consideration of the issue of geometric implementation (Theorem 9.7 [13, p. 149]) of the manifold \( P_N \).

Theorem 1. Each of the following three conditions results in the other two:

(i) BDR-problem (1) is solvable with respect to statement functions

\[
(A, A_1, B, D_1, D_2, D_3, D_4, D_5) \in L_2;
\]
Among other things, with the optimal operator norm. The following particular case is also important in specific discussions:

**Corollary 1.** If \( \dim V_N < N_0 \), \( \Psi[V_N] \subset L_\infty(T,R) \) and there is a \( p \in [1, \infty) \), at which

\[
\Psi(\varphi_1 + \varphi_2) \leq L \rho \Psi(\varphi_1) + \rho \Psi(\varphi_2),
\]

then the BDR-problem (1) is solvable.

Note, at that \( p = 1 \), this property (in the context of quasi-ordering of \( \leq_L \)) is akin to the property of "sublinearity" [18, p. 400] of functional operators.

### 4 The Continuity Property of the Rayleigh–Ritz Operator

In the case of compactness of the projective manifold \( P_N \) (\( \dim P_N < N_0 \) is of equal value) it is natural to try linking this geometric property to the problem of constructing the lattice \( \mathcal{R}(P \Psi[P_N]) \) within the context of the Rayleigh–Ritz operator projectivization continuity conditions; below in Theorem 2, when selecting metric structure in the cone \( L_\infty(T,R) \), we resorted to Theorem 15, 16 [3, pp. 65, 67]; in this formulation, the convex cone \( L_\infty(T,R) \) forms a complete separable metric space.

**Theorem 2.** Let \( \dim P_N < N_0 \) and the convex cone \( L_\infty(T,R) \) be endowed with a topology induced by convergence in measure \( \mu \), or, equivalently, by the invariant metric

\[
\rho_{\mu}(\cdot) : L_\infty(T,R) \times L_\infty(T,R) \rightarrow R, \quad \rho_{\mu}(f,g) := \int_{T} |f(t) - f(t)(1 + |f(t) - f(t)|)^{\frac{1}{2}}| \mu dt.
\]

Then the operator

\[
P \Psi : P_N \rightarrow L_\infty(T,R)
\]

will be continuous if the dynamic bundle \( N \) is such that the following takes place:

\[
\forall \varphi \in V_N \setminus \{0\} : \supp \|\varphi\|_{\text{mod} \mu} = T, \quad (4)
\]

in particular, if

\[
\forall \gamma \in P_N : \supp P \Psi(\gamma) = T. \quad (5)
\]

It should be noted that Theorem 2 is the development of Theorem 3, which confirms its methodological importance in mathematical (a posteriori) modeling of complex dynamic systems. The first application of this result is the following statement.

**Corollary 2.** If, when performing (4) or (5), the operator \( P \Psi \) is one-to-one, then \( P \Psi \) is homeomorphism, and the fundamental group of metric
space \( (\mathcal{P}[P_N], \rho_T) \) is isomorphic to the additive group of whole numbers \( \mathbb{Z} \) at \( \dim \text{Span} N = 2 \) and the group of deductions \( \mathbb{Z}_2 \) at \( \dim \text{Span} N \geq 3 \). Moreover, space \( (\mathcal{P}[P_N], \rho_T) \) is orientable if the dimensionality of the linear shell \( \text{Span} N \) is even, and is non-orientable if this dimensionality is odd.

**Proof.** The homeomorphism of the operator \( \Psi \) follows from Theorem 3.1.13 [19, p. 199]. This allows one to calculate (by virtue of Theorem 2.3 [13, p. 47] and proof of the Theorem 12.1 [13, p. 174] the fundamental group of space \((\mathcal{P}[P_N], \rho_T)\); as homeomorphic spaces are the spaces of the same homomorphic type. ■

**Corollary 3.** The ultimate projectivization \( \mathcal{P}[P_N] \to L_1(T, R) \) is continuous if for the arbitrary function \( \Phi \in \mathcal{V}_N \setminus \{0\} \) and any \( t \in T_0 = \{ t \in T : \Phi(t) = 0 \} \) there is a number \( \delta_{0, t} > 0 \) such that \( \mathcal{I}(t - \delta_{t, t}, t + \delta_{t, t}) \cap T_0 = 0 \). At the same time, \( \mathcal{P}[P_N] = [f(T)] \), where \( F \subseteq \omega \) is the Cantor set, \( f : F \to \mathcal{L}_1(T, R) \) is some continuous mapping.

**Proof.** We will establish the fact of \( \mu(T_0) = 0 \) (which is equivalent to (4)). To do this, we will select the number \( \delta_{t, t} > 0 \) to each moment \( t \in T_0 \) so that

\[
\mu((t - \delta_{t, t}, t + \delta_{t, t}) \cap T_0) = 0.
\]

Next, we'll find such rational numbers \( r_{t, t, r_{t, t}} \), that \( r_{t, t} \in (t - \delta_{t, t}, t + \delta_{t, t}) \), and let \( I_t = (r_{t, t}, r_{t, t}) \). Then the family of intervals \( \{I_t\}_{t \in T_0} \) covers the set \( T_0 \), and since each interval of \( I_t \) is open with rational end points, the family \( \{I_t\}_{t \in T_0} \) contains a certain countable subfamily of \( \{I_t\}_{t \in T_0} \), which is also the cover of the set \( T_0 \).

Since for any index \( i = 1,2, \ldots \) the inclusion of \( I_{t_i} \subseteq \cup_{i=1,2, \ldots} I_{t_i} \), is made, then, evidently, the equality \( \mu(I_{t_i} \cap T_0) = 0 \) occurs, and it means that the chain of \( \mu \)-relations is fair:

\[
\mu(I_{t_i}) = \mu(I_{t_i} \cap T_0) = \mu(\cup_{i=1,2, \ldots} I_{t_i} \cap T_0) \leq \sum_{i=1,2, \ldots} \mu(I_{t_i} \cap T_0) = 0 \Rightarrow \mu(T_0) = 0.
\]

Since the compact manifold \( P_N \) is locally arranged as a finite-dimensional Euclidean space, the equality of \( \mathcal{P}[P_N] = [f(T)] \) can be determined with Theorem 4.11 [13, p. 77] and Theorem 9.7 [13, p. 97]. ■

Taking into account that the continuous real function in the compact space reaches its greatest and lowest values, we come to the conclusion that in the formulation of Corollary 3 and Theorem 3.1.10 [19, p. 199], for the case when \( 1 \leq \dim P_N < N \), and with \( \sup_{\gamma \in P_N} \mathcal{P}[P_N] \), there will be such points \( \gamma', \gamma'' \in P_N \) that the following is fulfilled:

\[
\rho_T(\mathcal{P}[P_N](\gamma')) = \sup \mathcal{P}[P_N](\gamma), \quad \gamma, \gamma' \in P_N \leq \rho_T(\sup \mathcal{P}[P_N]) < \rho_T(\sup \mathcal{P}[P_N]), \quad \mu(T) - \rho_T(\mathcal{P}[P_N]), \quad \mu(T) = \inf \rho_T(\mathcal{P}[P_N]).
\]

It should be noted that the inclusion of \( \mathcal{P}[P_N] \) in \( L_2(T, R) \) does not guarantee an embedding \( R(\mathcal{P}[P_N]) \subset L_2(T, R) \).

At the same time, it should be noted that the condition \( \dim P_N = 0 \) leads to an important proposition

\[
\sup_{\gamma \in P_N} \mathcal{P}[P_N] = \mathcal{P}[P_N] = \left\{ \left( \sum_{i=1}^{n} \mu_{i} \right)^{\frac{1}{2}} \left( \sum_{i=1}^{n} \left( \sum_{i=1}^{n} \mu_{i} \right)^{\frac{1}{2}} \right) \right\}.
\]

Within the context of Theorem 1, 2, one can clarify the conditions of the existence of the lattice \( R(\mathcal{P}[P_N]) \). As a starting point, we introduce an auxiliary topological construction, namely, for the natural \( n \) let \( W_n \) denote some finite \( n-1 \)-dense [19, p. 395] subset in metric space \((P_N, \rho_T)\). The subset \( W_n \) is found in the virtue of Theorem 2 and Theorem 4.3.27 [19, p. 408]. Below, \( \lim_{n} \{\xi_n\} \) means the limit of sequence \( \{\xi_n\} \subset L_1(T, R) \) in the topology induced by the metric \( \rho_T \).

**Corollary 4.** Let

\[
W_{n+1} = \left\{ \xi_{1}, \ldots, \xi_{n} \right\} \subset \mathcal{P}[P_N], \quad f_n = f_{1} \cup \ldots \cup f_{n}, \quad \xi_{1} = \xi_{1} \cup \ldots \cup \xi_{n}, \quad \mu(T).
\]

Then the cone \( L_1(T, R) \) contains the lattice \( R(\mathcal{P}[P_N]) \) if and only if \( \rho_T(f_n, f_{in}) \to 0 (n, m \to \infty) \), besides, the BDR-solvability takes the following form: the pair \( (N, \tilde{A}) \) has a differential realization (1) then and only then, when \( \lim_{n} \{f_{n}\} \in L_1(T, R) \), which is equivalent to \( R(\mathcal{P}[P_N]) \subset L_2(T, R) \).

In concluding, here are the examples illustrating (in some essential ways) the possible analytical approach in the functional analysis of the pair \( (N, \tilde{A}) \), leading to the use of Theorems 1, 2.

**Example 1.** Let

\[
L_1(T, R) = \{f, g \in L_1(T, R) | L_1(T, R) \} \sup \mathcal{P}[P_N] : \text{mod}\n.
\]
L_\infty(T,R) is not a linear space, but it contains them (including infinite-dimensional ones).

Let us take a look at the functional operator 
\psi:L_\infty(T,R)\to L_\infty(T,R)
with construction of the form:
\psi(f,g)(t) = f(t)g^1(t) at g(t) \neq 0,
\psi(f,g)(t) := 0 for g(t) = 0;
With Lemma 2 in mind, this structure is induced by the operator (2).

Next, let us introduce the sequence \{(f_n,g_n)\} \subset L_\infty(T,R), for which the following holds true:
\rho_\psi(f_n,f_m) \to 0, \quad \rho_\psi(g_n,g_m) \to 0 (n,m\to\infty).
Moreover, taking into account the completeness of the metric space (L_\infty(T,R),\rho_\psi), we will require that
(\quad \text{Lim} \rho_\psi(f_n), \quad \text{Lim} \rho_\psi(g_n) \rangle \in L_\infty(T,R);
for convenience, let us denote
f' := \text{Lim} \rho_\psi(f_n), \quad g := \text{Lim} \rho_\psi(g_n).
In this formulation, for convergence
\rho_\psi(\psi(f_n,g_n), \psi(f,g)) \to 0 (n \to \infty)
it is enough to
\lim\{\mu(\text{supp} g \Delta \text{supp} g): n \to \infty\} = 0, \quad (7)
where \Delta is the symmetric difference of \text{supp} g_n and \text{supp} g, i.e. (\text{supp} g_n \setminus \text{supp} g) \cup (\text{supp} g \setminus \text{supp} g_n).

Although condition (7) is interesting and useful [20], unfortunately, it is not necessary, which indicates that there is a certain "excess" of conditions (4), (5) of Theorem 2. Within this context, there is an open issue of constructing a characteristic condition for the pair (\{f_n,g_n\}, (f,g)) that defines the \rho_\psi-convergence of the following form:
\rho_\psi(\psi(f_n,g_n), \psi(f,g)) \to 0 (n \to \infty).

\textbf{Example 2.} Let T = [0,10], Y = X, \hat{A} is the identical operator (homothetic transformation with coefficient 1 [18, p. 87]), e \in X, \|e\|_X = 1 and \hat{A}_1 = 0 \in L(X,X),
D_1 = D_3 = D_4 = D_5 = 0 \in \mathcal{L}(X^2, X),
t \mapsto x(t) = (t \sin t)e, \quad t \mapsto u(t) = 0 \in L_2(T,X).

Then (see Fig. 1)\textsuperscript{3} the function
f := \sup_{P_n} P\Psi(P_n) =
\||d^2x/dt^2||_X (||x||^2_0 + ||x||_1^2 ||dxd\hat{t}||_0^2 + ||u||^2_0)^1/2 \in L_2(T,R),
and, according to Theorem 1, differential realization (1) for the controlled dynamic process \quad t \mapsto (x(t),u(t)) exists; it is easy to establish that the realization has the form of:
d^2x/dt^2 + x = 2u - 2D_2(x, dxc/dt),
D_2 = \langle \psi, \psi \rangle_X e, \quad \langle \psi, \psi \rangle_X is the scalar product in X.

\textbf{Example 3.} Let us change (see Fig. 2) the formulation of Example 2 by the fact that
\quad t \mapsto u(t) = (t \sin t)^2 + 2 + (t \sin t)^2 (\sin t + t \cos t)^2)^{-1}
Then, obviously, we have
f := \sup_{P_n} P\Psi(P_n) =
\||d^2x/dt^2||_X (||x||^2_0 + ||x||_1^2 ||dxd\hat{t}||_0^2 + ||u||^2_0)^1/2 \in L_2(T,R),
and, according to Theorem 1, differential realization (1) for the controlled dynamic process \quad t \mapsto (x(t),u(t)) exists; it is easy to establish that the realization has the form of:
d^2x/dt^2 + x = 2u - 2D_2(x, dxc/dt),
D_2 = \langle \psi, \psi \rangle_X e, \quad \langle \psi, \psi \rangle_X is the scalar product in X.

\textsuperscript{3}The symbolic calculations of the function f^2 (\cdot) can be carried out (by computer algebra) using a special software environment [21], adapted to automate the problem-solving of analytical mechanics.

\textsuperscript{2}The condition (7) becomes necessary to perform the convergence
\rho_\psi(\psi(f_n,g_n), \psi(f,g)) \to 0 (n \to \infty), if to overload the sequence \{f_n\} by the additional proposition: there is such \delta > 0 for which f_n(t) \geq \delta for any n and \mu of almost all t \in \text{supp} g (see Remark 2 [20]).
Example 4. Let us assume that \( N = \{(x,u)\} \) and \( \hat{A}_1, \hat{A}_2 \in L_\omega(T, L(X,Y)) \) are set on the interval \( T = [0,1] \), and also for \( (N,\hat{A}_1,\hat{A}_2) \) there will be such \( \theta_1, \theta_2, \theta_3, \theta_4 \in L_\omega(T, R) \) that

\[
\begin{align*}
&\ t \mapsto t \theta_1(t), \\
&\ t \mapsto t \theta_2(t), \\
&\ t \mapsto \hat{A}_1(t)d^2x(t)/dt^2 + \theta_2(t), \\
&\ t \mapsto \hat{A}_2(t)d^2x(t)/dt^2 + \theta_4(t),
\end{align*}
\]

with that, there are real numbers \( \delta, \epsilon > 0 \), for which

\[
\mu \{ t \in T : \theta_2(t) + \theta_3(t) < \delta \} = \mu \{ t \in T : \theta_4(t) + \epsilon \} = 0.
\]

Then it is not difficult to establish (by virtue of Theorem 1, as well as by functional relations (6)), that the problem of BDR-model is solvable for the pair \((N,\hat{A})\) and is not solvable for the pair \((\bar{N},\bar{A})\).

5 Conclusion

A qualitative theory of non-linear non-stationary differential realization, considered in the spirit of the infinite-dimensional proposition of the reverse problems of mathematical physics, is more complicated, interesting, deeper in the applications and is very important for understanding the basic properties of the differential models themselves. Its geometric structures can serve as the starting points for the differential models themselves. Its geometric intuition is developed during the analysis of physical systems (in keeping with Chapter III [22]), simultaneously creating a reputation for these structures as a useful mathematical tool in the precision a posteriori modeling of complex dynamic models.

Since in many practically important objectives of realizing the differential representation of the simulated dynamic processes it is necessary to take into account the nonlinear relationship both from the trajectory itself and the speed of motion on it, and from program control, then the main attention was focused on the study of the realization model, which depends on five non-stationary bilinear structures. Moreover, one of them is set on the trajectory itself, the second bilinear operator depends on the trajectory and the speed of motion on it, the third bilinear operator depends only on the speed of motion along this trajectory, and the other two take these variables into account in the program controlling influencing them.

On the other hand, the goal of the article was also, without going into numerous clarifying details and avoiding the morass of mathematical generalizations, to advance in studying the qualitative geometric properties of a non-stationary second-order BDR-model as far as possible without involving a complex topological-algebraic technique.

Even now it is possible to quite confidently indicate system-theoretical direction, which will form the basis of the next stage in the development of a qualitative theory of the implementation of higher orders, namely, transition from the bilinear structure of non-linear bonds to the multi-linear structure. Methodologically, this transition lies in the plane of use of the language of tensor structures of Fock spaces [4, p. 68] and projective ideas [13, 16]. This language in this statement of nonlinear precision differential modeling of the dynamics of controlled infinite-dimensional continuous behavioristic systems should be given credit. On the one hand, it is compact and relatively flexible, and on the other hand, it is in its analytical constructions that the geometrical intuition is developed during the analysis of infinite-dimensional vector fields, which is one of the main driving forces for further synthetic development of the general theory of nonlinear differential realization. Such qualitative investigations suggest a deep penetration into the physical content of the subject [1], guided by the idea that the subject of non-stationary multilinear differential realization comes from the apodictic simplicity of some higher kind, at least if you adhere to Popper's point of view \(^4\).
